Steel facade system with spacer strip ZL
Stabalux ZL-S system description

- Stabalux ZL-S is a simple and affordable add-on system for single* and double glazing with a complete and customisable range to create facades and roofs with a steel supporting structure.
- The Stabalux ZL-S system is available in 50, 60 and 80 mm widths.
- The spacer strip is attached centrally to the sub-structure to ensure precise seals are made. Together with the seal, this provides a uniform appearance.
- The system can be installed on the construction site without any prior processing of the sub-structure and is therefore an ideal choice for facade refurbishment work.

¹ Without effect of screws

* only works without the use of threaded sockets
Stabalux ZL-S System

System properties

Certifications, authorisations, CE mark (Section 9)

The tests we have conducted provide the processor and planner with the certainty and the ability to use the test findings and the products fits, for instance to award the CE mark.

Permeability/Safety

- The Stabalux sealing geometry prevents moisture ingress.
- Condensation is guided away in a controlled manner.
- Stabalux offers slotted and overlapping sealing systems for vertical glazing. Overlapping systems have been tested for inclined facades up to 20°.
- Transom flags increase the safety and impermeability of the installation on vertical glazing.
- A special Stabalux sealing system with offset sealing sections is used for roof glazing. This keeps the supporting structure level during planning and production processes.
- Sealing the transom rebate allows flat roofs to be created with an incline of up to 2°.
- Creation of the required drainage takes place directly at the construction site by pushing together the seals in the facade or slotting together the offset sealing sections in the roof.

Insulation/Thermal Separation (Section 9)

The Stabalux System ZL has excellent thermal properties. It allows a heat transfer coefficient of $U$, for frames of up to 0.60 W/(m²K).

Noise insulation of the glass facade (Section 9)

The noise insulating properties of a facade depend on a variety of factors, each of which affects the properties in a different way. The task of the planner is to expertly select the optimum design on a case-by-case basis. Different combinations of frame profiles, glazing systems and noise reducing glass have vastly different effects on noise insulation. Investigations and measurements performed by us are just examples of a huge range of possibilities and serve only as a guideline.

Stabalux SOL sun protection (Section 9)

We offer our proprietary system with exterior lamellae, in addition to the familiar measures for protection against glare and excessive sunlight. Particular attention has been paid here to ensure attachment and assembly can be completed easily with Stabalux systems whilst meeting architectural and climatic requirements. Glass panes and clamping strips are not subject to any load from application of the sun protection. Assembly and sealing are simple and efficient.

ZL-S_2.1_005.dwg
Material information

Quality of the supporting structure

The steel load-bearing substructure is used for mounting the glazing and must meet all load and suitability requirements. The static system, profile dimensions and choice of materials are key. The client, architect and/or processor is responsible for this decision.

The following limit values must be adhered to in the selection of the steel type:
- Rated values of yield strength \( f_y \geq 235 \text{ N/mm}^2 \);
- Tensile strength \( f_u \geq 360 \text{ N/mm}^2 \).

We recommend selecting materials according to Eurocode 3 (DIN EN 1993).

The cross-sectional geometries and dimensions of the supporting profiles should also enable dimensioning according to Eurocode 3.

Corrosion protection and coating on the supporting structure

Mullion and transom constructions usually receive a coloured coating for aesthetic reasons. Galvanization is used to improve anti-corrosion where necessary. The following corrosion protection options are therefore conceivable:
- Colour coating on supporting profiles with strip-galvanized surface.
- Colour coating on supporting profiles with dip-galvanized surface.
- Supporting profiles with galvanized surface but without colour coating.
- Colour coating on supporting profiles with non-galvanized surface.

Conventional coating methods such as air-drying multi-layer coating systems (wet coating) or thermosetting coatings (stove enamelling / powder-coating) can be used, provided suitable pre-treatment is applied.
Material information

Profile design

The diagram below shows some examples for the geometry of supporting profiles. The profiles must be protected against corrosion and free of dirt.

The spacer strips can also be mounted onto existing profiles.

Spacer strip quality

Stabalux spacer strips are made of hard PVC, unpunched, in black - suitable for a uniform visual appearance for inner Stabalux seals.

Seal profiles

Stabalux seals are organic natural rubber materials based on EPDM and conform to the DIN 7863 standard, non-cellular elastomer sealing profiles for window and facade construction. Compatibility with contact media should tested by the processor, particularly when using plastic glazing and making structural joints with non-Stabalux products. Sealing the rebate with all weather silicone seal is possible.

All weather silicone seal

Only certified materials may be used for sealing the rebate with all-weather silicone. Pay attention to all information provided by the manufacturer and the sealing work must be carried out by trained persons. It is recommended that a licensed and certified specialist contractor is hired for this purpose. We further refer you to the DIN 52460 standard and IVD data sheets (Trade Association for Sealants). The compatibility of the materials is particularly important when using all-weather silicone. In this case, the compatibility of the sealant with the edge bonding of the glass and the backfill of the joints. If self-cleaning glass is used, the compatibility must be established in advance. Glass sealants and edge bonding must be UV-resistant. The incline of roofs should also be taken into account. Information about UV-resistance can be requested from the manufacturer. Silicone edge bonding generally provides better UV-resistance than polysulfide-based materials. The advantage of silicone lies in its high vapour sealing properties which is particularly useful when using more volatile argon fillings. Highly elastic, weatherproof and UV-resistant seals meet the widest range of demands for reliable joints.

Aluminium profiles

The aluminium profiles we supply are generally made from EN AW 6060 according to DIN EN 573-3, T66 according to DIN EN 755-2.

Coating the aluminium

Alongside anodic oxidation, with the corresponding pre-treatment, conventional coating methods such as air-drying multi-layer coating systems (wet coating) or thermosetting coatings (stove enamelling / powder-coating) can be used. By using different mass distribution, longitudinal shadow formation is possible with cover profiles DL 5073 and DL 6073. Resulting actions are to be taken with the agreement of the coater.
**Longitudinal expansions in aluminium profiles exposed to temperature stress**

When cutting the lower, upper and cover profiles from aluminium, allowance should be made for temperature-induced longitudinal expansion. The theoretical rod lengths \( l \) should be shortened by: \( \Delta l = \alpha_T \cdot \Delta T \cdot l \).

**Example:**

\[
\Delta l = 24 \cdot 10^{-6} \cdot 40 \cdot 1000 = 0.96 \approx 1 \text{ mm}
\]

\( \alpha_T \approx 24 \cdot 10^{-6} \quad 1/K \)

Coefficient of thermal expansion for aluminium

\( \Delta T = 40 \text{ K} \)

Assumed temperature difference of aluminium dependent on the colour and amount of solar radiation

\( l = 1000 \text{ mm} \)

Rod length

\( \Delta l \approx 1 \text{ mm} \)

Longitudinal expansion

**Further examples:**

\[
\begin{align*}
\Delta l &= 24 \cdot 10^{-6} \cdot 60 \cdot 1000 = 1.44 \approx 1.5 \text{ mm} \\
\Delta l &= 24 \cdot 10^{-6} \cdot 100 \cdot 1000 = 2.4 \approx 2.5 \text{ mm}
\end{align*}
\]

A rod with a system length of \( l = 1000 \text{ mm} \) should be shortened by 1 mm for a temperature difference of \( \Delta T = 40 \text{ °C} \). A rod of length \( l = 3000 \text{ mm} \) should be shortened by 3 mm.

For \( \Delta T = 100 \text{ °C} \) (often occurs in roof areas and south-facing facades), a rod of length \( l = 1000 \) should be shortened by 2.5 mm.

**Material information**

<table>
<thead>
<tr>
<th>Rod length ( l ) (mm)</th>

</tbody>
</table>

**Note:**

We recommend shortening the lower strip by \( \approx 2.5 \text{ mm} \) per \( l \approx 1000 \text{ mm} \) of length. When doing so, ensure to use the correct length of the outer seal.

When using cover profiles in roof area, it is recommended that holes for screwing on the cover strip are created with a diameter of \( d = 9 \text{ mm} \).

**Stainless steel profile**

Pressure profiles and bottom sections of cover profiles are made from 1.4301 stainless steel for visible screw fittings. The surface is equivalent to classification 2B according to DIN 10088-2.

Cover profiles using 1.4401 stainless steel. The surface has a ground finish (grain 220, DIN EN 10088-2). The upper parts of the cover profiles are made from 1.4571 stainless steel with ground finish (grain 240, DIN EN 10088-2). A film is attached on one side to protect the surface; its knife edge remains visible on one narrow side.

**Other items**

All system items are produced according to applicable standards.

**Maintenance and care**

The information sheets WP.01 – WP.05 from the Association of Window and Facade Producers (VFF) must be observed. The address can be found in the address section. Further information can be found in section 9.0 - Cleaning / Maintenance.
Assembly sequence

1. Threaded bolts M6, i.e. threaded welding studs must be fastened to the primary steel supporting structure. Pay attention to the intervals between the bolts. The length of the bolts is variable and depends on the height of the inner seal (refer also the section of screw technology).
2. Carry out preparatory work on the steel profiles to suit the statically required glass supports.
3. Drill holes must be prepared for the spacer strips, e.g. ZL 6053 with Ø 7mm, in the same intervals as for the threaded bolts, and the spacer strips are then placed over the threaded bolts (fasteners). The spacer strips are positioned continuously in a vertical direction and abutted in a horizontal direction.
4. Installation of the inner seal, e.g. GD 6025.
5. Screw the threaded sockets (e.g. Z 0032, M6 with wrench opening M10, length 25 mm) on to the threaded bolts/threaded welding studs on the supporting steel construction.
6. Screw the threaded bars e.g. Z 0036 into the threaded bars sockets and pay attention to the clamping length. This depends on the glass thickness and the clamping strips.
7. Attach the glass support e.g. Z 0888.
8. Mounting the filling elements.
9. Lay the outer seal, e.g. GD 6024 together with the clamping strips.
10. Attach the clamping strips (cover profiles e.g. DL 6061, bottom strips, e.g. UL 6009 L) using sealing washer, e.g. Z 0086 and cap nut Z 0043.
11. Clip on the upper strip, e.g. OL 6013, with concealed screw fittings.
Attaching the spacer strip

Mounting to the supporting structure

- Attach the threaded welding studs M6 according to building approval specifications and/or technical regulations, i.e. supplier instructions. Make threaded holes or threaded blind holes in the steel supporting structure in order to attach the threaded bolts M6.
- Carry out preparatory work on the steel profiles to suit the statically required glass supports.
- Drill holes must be prepared for the spacer strips with $\varnothing$ 7mm, in the same intervals as for the threaded bolts, and the spacer strips are then placed over the threaded bolts.
- The distance for screw fittings is variable. The maximum distance is $a = 250$ mm.
- The distance from the edge for the first screw fitting should generally be in the region of $30 \text{ mm} \leq e \leq 80 \text{ mm}$. The placement of the glass supports should also be taken into account. The mullion-transom joints in the structure must also be taken into consideration when selecting the distances.
- The spacer strips are positioned continuously in a vertical direction and abutted with the mullions.
- The length of the spacer strip corresponds to the length of the substructure for mullions and transoms.
Sealing system principle, general information about glazing seals

The Stabalux sealing system consists of the outer and inner sealing sections:

- The outer sealing section has the primary function of preventing the ingress of moisture. At the same time, the sealing section provides a flexible support for the glass panes.

- The inner sealing section acts to protect the inner space, water guiding section and elastic glass supports from moisture and vapour.

Both sealing sections must perform this function over a long period of time.

Seals should be adapted on the construction site, but may also be pre-cut to the required length in the factory and pulled into the spacer strips and/or clamping strips following the mounting instructions for seals. Always ensure that seals are not bearing any loads once installed and are firmly pressed onto joints. All joints should be sealed as per the following descriptions.

Pressure equalisation and controlled drainage

Pressure equalisation is generally achieved via openings at the base, head and ridge points. Should additional ventilation be required in the area of the transom (e.g. where panes are only supported on 2 sides or where transom length is $\ell \geq 2$ m), then this ventilation should be created by placing holes into the cover strip and/or using notches on the lower sealing lips of the outer seal.

The pressure equalisation openings also serve to drain away moisture. The inner sealing section is formed in such a way that when the joints are properly sealed, any moisture that occurs and does not dissipate via the rebate ventilation will drain away downwards. In facades, water is guided via the transom flag into the mullions. There is a choice between using tested sealing systems with between 1 and 3 levels. With inclined glazing with 2 drainage levels, the higher sealing section of the transom overlaps the lower mullion seal. These principles must be consistently implemented down to the lowest point of the glazing so that the water-guiding level of the structure carries moisture to the outside. Film is placed beneath the seals accordingly. It must be ensured that the film will last for a long time.
Tips for laying seals

Inner sealing section

The structure of the inner sealing section is different for vertical facades and facades with an inward incline up to 20° as well as roof glazing.

Inner sealing for vertical glazing and glazing with an inward incline up to 20°:

- 5 mm butt jointed seals with a drainage section for vertical facades ($\alpha=0^\circ$)
- 10 mm high seals with two drainage sections to safely guide away any moisture or condensation to the outside. These seals are created by overlapping the seal joints in which the higher sealing section of the transom goes underneath the lower level of the mullion. These seals can be used for vertical facades and facades with an incline up to 20°.
- 12 mm high seals follow the same principle, but allow an additional third drainage section for an intermediate mullion.
- The shaped transom flag protects the vulnerable area of the rebate and ensures that moisture is drained away via the vertical or up to 20° inwards inclined mullions.

Inner seals for glazed roofs:

- A special seal geometry for glazed roofs also allows for two-level stepped drainage. The 10 mm high seals are laid with overlapping joints.

Some basic information for sealing and sticking down Stabalux seals

- All joints and seal penetrations must be waterproofed. An exception to this is the Stabalux system screw fittings where the hole diameter of the inner seal is at most the same as the core diameter of the M6 thread of the bolts and the seals are laid close together.
- Gasket joints are should always be sealed using Stabalux sealant, regardless of whether they are butt joints or overlapping. (We recommend Stabalux connecting paste Z 0094. Pay attention to the directions provided by the manufacturer).
- For difficult to seal places we recommend first using a fixing adhesive such as the Stabalux quick fixing glue Z 0055.
- Before gluing, ensure all surfaces are free from moisture, dirt and grease.
- Weather conditions such as snow and rain prevent an effective seal.
- Temperatures below +5 °C are not suitable for fixing seals.
- The hardened connecting paste should not prevent level support of glass.
Assemble the inner seal on vertical facade glazing - 1 level join

- The horizontal transom seals are laid continuously across the mullion-transom joints. Ensure here that the clamping feet of the horizontal seal are released around the mullion.
- Mullion seals are butt jointed to the transom seals.
- The transom flags should be released to a width of 10-15 mm at the mullion joint.
- The protruding length of the transom flag should be removed at the perforation once glazing is completed.

- In order to safely drain away moisture from transoms even at the edges of the facade, the inner transom seals must be laid into the released mullion seals. To release and remove the clamping feet we recommend using our release pliers Z 0078 for System 60 and Z 0077 for System 50.
- Ensure all joints are cleanly and solidly sealed. Excess sealant should be removed.
Seals - Facade

Assemble the inner seal on vertical facade glazing - 1 level join

Note
Any joints in the transom seal that are required due to the delivered length should be fitted with an intermediate mullion and put together like in point A.

The transom flag should always cover the inset "e" of the filling element (e.g. glass panes, panels)

Release edge mullion seal near transom

Edge mullions

Intermediate mullions

Transom

Seal gasket joints

edge mullion seal around a transom near transom

Seal gasket joints
Assembly of the inner seal for vertical facade glazing and facade glazing with an incline of up to 20° - 2 overlapping sections

- The 10 mm high seals can be divided across their height to allow a simple overlap at critical transom joints.
- The vertical seals for the mullions (2nd drainage section) are laid continuously.
- The transom seals overlap the mullion seals.
- Moisture and condensation is guided away via the transom flag of the transom seal (1st drainage section) to the main mullion.
- The transom flag must always cover the inset depth of the glass panes and filling element.
- The protruding length of the transom flag should be removed at the perforation once glazing is completed.
- All joints must be sealed. Before laying seals, we recommend completely coating the entire support surfaces and sides with Stabalux connection paste.
- Ensure all joints are cleanly and solidly sealed. Excess sealant must be removed. Absolutely no unevenness in the glass support surface must occur from applying sealant too thickly.
Assembly of the inner seal for vertical facade glazing and facade glazing with an incline of up to 20° - 2 overlapping sections

Seal gasket joints, overlapping joints

The transom flag should always cover the inset "e" of the filling element (e.g. glass panes, panels)

Mullion seals around a transom upper section to the width of the transom seal

Transom seal separate lower section at length of the overlap "e"

Edge mullions

A

Intermediate mullions

B

Transom

Transom seal separate lower section at length of the overlap "e"
Assembly of the inner seal for vertical facade glazing and facade glazing with an incline of up to 20° - 3 overlapping sections

- Optionally, Stabalux seals with three offset water channels can be used in the facade area which safely drain any moisture or condensation to the outside.
- The 12 mm high seals can be divided across their height to allow a simple overlap at critical secondary mullion/transom joints, i.e. transom/primary mullion joints.
- The vertical seals for main mullions (3rd drainage section) are laid continuously.
- The transom seals overlap the main mullion seals.
- Along a transom, seals must be laid continuously.
- Moisture and condensation is guided away via the transom flag of the transom seal (2nd drainage section) to the main mullion.

Seal gasket joints

1. inner continuous mullion seal, inner overlapping transom seal clipped in
2. The transom flag should always cover the filling element
3. Secondary mullion seal is clipped into the transom seal with an overlap
Assembly of the inner seal for vertical facade glazing and facade glazing with an incline of up to 20° - 3 overlapping sections

- The transom flag must always cover the inset depth of the glass panes and filling element.
- The protruding length of the transom flag should be removed at the perforation once glazing is completed.
- Vertical seals on the secondary mullion are butt jointed beneath the upper transom. The transom flag of the upper transom runs continuously in the upper part of the joint.
- Drainage of the secondary mullion (1st drainage section) is achieved by overlapping the seals of the secondary mullion with the seal of the upper transom.
Seals - Facade

Assembly of the inner seal for vertical facade glazing and facade glazing with an incline of up to 20° - 3 overlapping sections

- All joints must be sealed. Before laying seals, we recommend completely coating the support surfaces and edges with Stabalux connection paste.
- Ensure all joints are cleanly and solidly sealed. Excess sealant must be removed. Absolutely no unevenness in the glass support surface must occur from applying sealant too thickly.

Separate the main mullion seal around the upper section of the transom to match the width of the transom seal.

The transom flag should always cover the inset "e" of the filling element (e.g. glass panes, panels).

ZL-S_2.2_005.dwg
Assembly of the outer seal for vertical facade glazing

- As well as gently clamping the glass in place, the outer sealing system has the primary task of protecting the rebate against moisture ingress.
- The outer sealing sections must be completely sealed except for the necessary openings for pressure equalisation and condensation dissipation.
- The outer mullion seals are laid continuously and the transom seals are joined.
- Sealant joints are to be laid flat with a slight excess in dimensions. Exact specifications depend on the situation in which the system is used.
- It is not necessary to glue the outer sealing in the mullion-transom joint if the sealant joints fit precisely.
- The flag for the inner transom joint in combination with the outer seal creates additional safety.
- The transom flag should be separate at its perforations to match the thickness of the glass in order that this is clamped down and concealed under the outer seal.
- Different heights of sealing lips on the outer seal bridge the height different created by the transom flag in the outer sealing section.
- Differently high, split seals allow a balance between filling elements of different total thickness of up to 6 mm.
- When mounting the clamping strip, be aware of aluminium profile expansion (see section 2.2.1 - Material information)
Seals - Facade

Assembly of the outer seal for facade glazing with an inwards incline of 20°

- If the facade is inclined inwards from the vertical (max. permitted incline 20°), the open ends of the outer transom seals must be closed up using butyl.
- When constructing inwardly inclined facades (up to max. 20°), if flat cover profiles are used in the transoms (e.g. DL 5059, DL 6059, DL 5061, DL 6061, DL 5067, DL 6067, DL 5071, DL 6071, DL 6043, DL 6044) and flat lower and upper strips (e.g. UL 6005 with OL 6066), then the central hollows at each end must be sealed with silicone.

Trim the seals to be slightly larger than required.

When using flat cover profiles on inwardly inclined facades (up to max. 20°), the central hollow at each end should be sealed with silicone.
Seals - roof

Assembly of the inner seal for roof glazing

- Optionally, Stabalux seals with offset water channels can be used in the facade area which safely drain any moisture or condensation to the outside.
- The 10 mm high seals can be divided across their height to allow a simple overlap at critical transom joints.
- The transom seals are geometrically shaped so as to create a condensation channel.
- This channel drains from the overlapping transom joint in the rafters.
- Along a transom, seals must be laid continuously.
- All joints must be sealed. Before laying transom seals, we recommend applying a thin coating to the entire support surfaces. Absolutely no unevenness in the glass support surface must occur from applying sealant too thickly.

1. remove the lower perforated part and the clamping foot on the transom seal at around 15 mm
2. remove the upper perforated part on the rafter seal
3. Length of transom seal = transom length + ~13 mm per side

Seal gasket joints

ZL-S_2.2_008.dwg
Seals - roof

Assembly of the outer seal for for glazed roofing

- These are laid in fundamentally the same way as for vertical glazing. Split seals such as GD 1932 are not suitable for transom seals in roofs. Split seals can only be installed in mullions in combination with slab insulation. Each installation situation will differ to some degree and always check how well sealed it is.
- For cross joints we recommend using our self-adhesive stainless steel sealing plates with butyl coating Z 0601 for System 60 and Z 0501 for System 50. The stainless steel sealing plates are 35 mm wide and are attached to the edge of the glass panes parallel to the mullion axis.
- Butyl tape is not suitable as a sealing tape between the glass and the outer seal.
- The outer mullion seals are laid continuously and the transom seals are joined.
- Sealant joints are to be laid flat with a slight excess in dimensions. Exact specifications depends on the situation in which the system is used.

Note:
- Horizontal clamping strips prevent the free run off of rain water and dirt.
- Cover strips and upper strips with angled edges reduce the build up of water in front of the clamping strip.
- Shorten the clamping strips on the transoms by 5 mm in the area of the transom joins in order to improve drainage of water. Gasket joints, however, are to be laid flat with a slight excess in dimensions. Open ends of transom clamping strips (upper and cover profiles) should be sealed.

Detail of sealing plate
Z 0501 = 35 x 40 mm
Z 0601 = 35 x 50 mm

Attention: The sealing plates must be glued central to the transom axis!

For glass insets of 15 mm, the first screw fittings for the transom cover strip begin 30 mm from the end of the cover strip.
Seals - roof

Assembly of the outer seal for inclined glazed roofing up to 2°.

- These are laid in fundamentally the same way as for vertical glazing. Split seals around the mullions in roofs such as GD 1932 are only suitable when using in combination with slab insulation. Each installation situation will differ to some degree and always check how well sealed it is.
- To ensure free run-off of rain water and dirt on roofs inclined up to 2°, we recommend not using clamping strips in the transoms.
- Instead, the rebate spaces should be sealed with all-weather silicone.
- Implementation of the outer sealing section around mullions is done in the same way as conventional roofs with an inclination up to 15°.
- At the high point or ridge area of the inclined glazing, it is recommended to also install an outer sealing section in the transoms with clamping strips.
- Only certified sealing materials may be used for sealing the transom rebate space.
- Pay attention to all information provided by the manufacturer and the sealing work must be carried out by trained persons. It is recommended that a licensed and certified specialist contractor is hired for this purpose. We further refer you to the DIN 52460 standard and IVD data sheets (Trade Association for Sealants).

Tips for all roof designs:

When using aluminium cover profiles on roofs, take account of the expansion factor as a result of the high degree of heat absorption when selecting the length to use. Equally, the use of single-piece cover profiles should be carefully considered. In this case it is recommended that holes for screwing on the cover strip are created with a diameter of \(d = 9\) mm. (see section 2.2.1 - Material information).

For wide spans we recommend using concealed screw fittings when selecting the clamping strips (lower + upper strip). This is the preferred option for rafters. Unused holes in the lower strip must be sealed.

Some roof areas, such as the eaves, see the use of several different materials (glass, silicone, aluminium sheets, ...) each with different expansion coefficients. To avoid the formation of cracks, aluminium sheets should be installed with expansion joints.
Assembly of the outer seal for glazed roofing up to 2° incline

- The compatibility of the materials is particularly important when using all-weather silicone. In this case, the compatibility of the sealant with the edge bonding of the glass and the backfill of the joints. If self-cleaning glass is used, the compatibility must be established in advance.
- Glass sealants and edge bonding must be UV-resistant. The incline of roofs should also be taken into account. Information about UV-resistance can be requested from the manufacturer. Silicone bonding generally provides better UV-resistance than polysulfide-based edge bonding. The advantage of silicone lies in its high vapour sealing properties which is particularly useful when using more volatile argon fillings.
- Highly elastic, weatherproof and UV-resistant seals meet the widest range of demands for reliable joints.
- If the silicone joint is created without additional mechanical safety devices, ensure that the glass is supported from two sides only. Selective installation of holding clamps can be used to provide support for all glass edges.
- The clamps are made from stainless steel with silicone washers and are screwed in the same as pressure strips. The hold-down clamp should be additionally sealed around the perimeter with silicone sealant. The design is based upon the dimensions of the glass as documented in the glass static analysis.

Seals - roof

Assembly of the outer seal for glazed roofing up to 2° incline

- The joint width and the joint height for Stabalux SR are defined as w x h = 20 mm x 10 mm. These measurements should always checked when selecting the sealing material and adapted if necessary. Generally: w : h = 2 : 1 to 3.5 : 1.
- PE round section seals or Stabalux slab insulation is suitable as a back fill material.
- Silicone sealant should be applied before laying the mullion seals and cover profiles.
- After the specified setting time, the seals and screw fittings can be installed in the areas around mullions.
- The mullion-transom joints around the clamps are then sealed.
- Before applying this second layer, the joints around transoms must have completely set.

Joint design according to manufacturers specifications!
Generally: w : h = 2 : 1 – 3.5 : 1
Steps for creating the seal with all-weather silicone

- Test the silicone sealant and glass edge bondings and other contact surfaces (e.g. panels) for suitability.
- Clean edge bonding adhesive impurities from the surfaces to which sealant will be applied following manufacturer’s directions.
- Fill the joints as per the joint dimensions using only non-water absorbent closed-cell PE profiles (no damage to the edge bonding).
- The remaining space in the glass rebate must be large enough that the pressure is able to equalise and a drainage level is available.

- Clean any impurities from the surfaces to which the sealing material is to be applied and any adjacent surfaces according to manufacturer’s directions.
- Be particularly aware of any adjacent metal components. Prime according to manufacturer’s directions.
- Seal joints without leaving any cavities or bubbles. Mask any adjacent components in advance where necessary.
- Smooth out the filled joints using the manufacturer’s smoothing agents and conventional tools with as little water as possible. Remove the adhesive tape when liquid.
- If two or more reactive sealants are used in combination, the first must completely set before the second is applied.
Glass inset and glass support

Glass inset

- Glass industry guidelines must be observed.
- The glass inset is generally 15 mm.
- An increase in the glass inset to 20 mm has a beneficial effect on the heat transfer coefficient $U_f$ of the frame structure.
Glass inset and glass support

Glass support types and selection of glass support

Glass supports carry the load of the glass panes through to the structure. The permissible glass weights also depend on the structure of the glass and the selected mullion-transom connection. The mullion-transom connection must be selected in such a way as to minimise any subsequent turning of the transoms. The depth of the glass supports is determined by the glass structure. Section 9 contains more information in this respect.

The Stabalux ZL-S system distinguishes between two different types and techniques for attaching glass supports:

- Glass support GH 5053, i.e. GH 5055 with 2 or 3 welding studs ∅ 10 mm.
- Heavy glass loads require welded glass supports. For this purpose, flat sheets with a thickness of t = 5 mm are welded on to the transoms.

Mounting the glass supports

- Positioning the glass supports and glazing according to glass industry guidelines and guidelines of the Institute for Window Technology.
- The weight of the glass panes is distributed via the glass supports attached to the transoms.
- Glass supports should be attached at an interval of 100 mm from the end of the transom. When doing so, avoid a collision with the cover strip screw fittings at the end of the transom.

Glazing blocks

- Glazing blocks must be compatible with the edge bonding of the insulated glass panes.
- They should be stable under constant pressure and be able to withstand loads, aging and temperature changes.
- It is important that the blocks ensure circumferential pressure equalisation and that drainage of condensation is not obstructed as well as allowing the glass edges to be offset and small design tolerances to be accommodated.
- If the length of the glass support is more than 100 mm, blocks should be placed along the entire length of the glass support to ensure equal load distribution.
Glass inset and glass support

Glass support GH 5053 with bolts

- The glass support consists of the Stabalux system component GH 5053 and 2 welding studs Ø10 mm, which must be made available on the building site.
- The glass supports GH 5073 are manufactured using aluminium in EN AW 6060 quality, condition T66.
- The depth of the glass supports depends on the installed thickness of the glass panes and the geometry of the inner seal. The required cuts are delivered to match glass support GH 5053.
- The bolts must be sufficiently protected against corrosion and be suitable for weld connections with the steel grade of the supporting structure. Stainless steel bolts must be used otherwise.
- The length of the bolts is calculated based on the installed thickness of the glass panes plus the height of the inner seal and the height of the spacer strip.
- The centre distance between the bolts is 80 mm.
- The bolts must be welded in the centre of the transom in the substructure to disperse the load from the glass. Screw fittings must be positioned vertically to the transom.
- The spacer strip should also be pre-drilled with Ø 11 mm holes at the relevant points to attach the bolts.
- Holes must be made at the relevant points of the transom seal. Here it is important to ensure that the holes have as precise a fit as possible. We recommend sealing the holes with Stabalux Z 0094 paste.
- The glass supports are mounted loosely on the building site once the spacer strip and the inner sealing section have been fitted.
- Blocks must be placed under the glass panes along the entire length of the glass supports.
- It is essential to ensure when installing the glazing that neither the glazing blocks nor the glass supports slip.
- The glass supports (bolts) must be validated for the glass thickness, the glass weight and the selected mullion-transom connection.
Glass inset and glass support

Glass support GH 5053 with bolts
Glass inset and glass support

Glass support GH 5055 with bolts

- The glass support consists of the Stabalux system component GH 5055 and 3 welding studs Ø10 mm, which must be made available on the building site.
- The glass supports GH 5055 are manufactured using aluminium in EN AW 6060 quality, condition T66.
- The depth of the glass supports depends on the installed thickness of the glass panes and the geometry of the inner seal. The require cuts are delivered to match glass support GH 5055.
- The bolts must be sufficiently protected against corrosion and be suitable for weld connections with the steel grade of the supporting structure. Stainless steel bolts must be used otherwise.
- The length of the bolts is calculated based on the installed thickness of the glass panes plus the height of the inner seal and the height of the spacer strip.
- Installation is performed the same way as GH 5053, but using three screws at intervals of 80 mm.

2) Cut from GH 5053 or GH 5055.
Glass inset and glass support

Welded glass support

- Welded glass supports made of flat steel that are welded on to the transom profiles. The glass supports must be made available on the building site.
- Flat steel in grade S235, i.e. matched with the quality of the supporting construction. It must be possible to weld the steel grades together. The weld seam must connect the entire cross section of the glass supports.
- The glass supports must be sufficiently protected against corrosion.
- The depth of the glass supports depends on the installed thickness of the glass panes, the geometry of the inner seal and the height of the spacer strip.
- The glass supports must be welded in the centre of the transom in the substructure to disperse the load from the glass. The glass supports must be positioned vertically to the transom.
- The spacer strip must be cut out at the relevant points so as to ensure that the glass support and the weld seam cannot collide.
- The transom seals must be cut out around the holes for the glass supports and then sealed using Stabalux connection paste Z 0094.
- Blocks must be placed under the glass panes along the entire length of the glass supports.
- It is essential to ensure when installing the glazing that the glazing blocks cannot slip.
- The width of the glass supports is at least 100 mm; their size must suit the static requirements.
- The glass supports must be validated for the glass thickness, the glass weights and the selected mullion-transom connection.
Glass inset and glass support

Welded glass support

1. Match the thickness of the glass support with the glass thickness.
2. Make the weld seam as even as possible, fully connect the cross section, mould the spacer strip around the glass supports.
3. Cut out the sealing around the holes for the glass supports and seal with Stabalux connecting paste.

Glass support
Block
Inner seal
Spacer strip

Width "W"
Glass inset and glass support

**Glass support GH 5055 with threaded bolt**

- The depth of the glass support must be matched with the thickness of the glass.

\[
T = \text{depth of the glass support} \\
T_1 = \text{height of the spacer strip} \\
T_2 = \text{height of the inner seal} \\
\quad \text{(e.g. 5 m, 10 mm or 12 mm)} \\
T_3 = \text{thickness of the glass pane}
\]

\[
T = T_1 + T_2 + T_3
\]

**Example:**
- Spacer strip \( T_1 = 10 \text{ mm} \)
- Inner seal (e.g. GD 6030) \( T_2 = 5 \text{ mm} \)
- Thickness of pane 6 / 16 / 6 \( T_3 = 28 \text{ mm} \)

\[
T = 10 + 5 + 28 = 43 \text{ mm}
\]
Screw fittings

Fastenings

- The system screw fittings are a combination of basic room-side screw fittings, a coupling using a threaded socket that allows thermal separation in the rebate and a flexible bolt-nut connection or screw connection on the glazing side.

Basic room-side screw fittings

- The threaded bolts M6 can be used for the basic room-side screw fittings; they are screwed into the threaded holes, i.e. the threaded blind holes. Welding studs M6 can be used alternatively.
- The length of the threaded bolts depends on the height of the spacer strip, the height of the inner seal and the material selected for the supporting structure (mullion and transom profiles), i.e. the selected depth of the blind holes, which must be ≥ 7 mm. Grade 1.4301 A2 stainless steel bolts must be used.
- In most cases the selected welding studs should have a length of 25 mm, and they must be made available on the building site. The bolts must be sufficiently protected against corrosion and be suitable for weld connections with the steel grade of the supporting structure. Stainless steel bolts must be used otherwise.

Coupling with threaded socket

- The threaded socket is delivered in a length of 25 mm and twisted tight on to the basic screw fittings without excessively compressing the inner seal. The Stabalux threaded sockets can be delivered in stainless steel (art. no. Z 0029) or plastic (art. no. Z 0032).

Bolt nuts, i.e. screw connections on the glazing side

- The assembly consists of a threaded bolt and optionally a sealing washer and a cap nut. Screws according to DIN 6912, stainless steel 1.4301 A2 can be used alternatively.
- Screws in the Stabalux system are produced using stainless steel, usually with the material number 1.4301 DIN EN 10088.
Concealed screw fittings

- Assembly is facilitated by the selection of pre-drilled clamping strips (e.g. UL 5009-L and UL 6009-L, slot 7 x 10 mm, a = 125 mm) with clipable upper strips. A round hole of d = 8 mm should be made in the remaining clamping strips. The functionality of the clip procedure can be checked after the first cover profile has been pushed against the lower strip.

Note:

When using aluminium cover profiles on roofs, take account of the expansion factor as a result of the high degree of heat absorption and its impact on the selected length. Equally, the use of single-piece cover profiles should be carefully considered. In this case it is recommended that holes for screwing on the clamping strip are created with a diameter of d = 9 mm.

Visible screw fittings

- Cover strips should be drilled with a round hole of d = 8 mm.

Note:

(see Note on concealed screw fittings)

Visible recessed screw fittings

- When creating visible recessed screw fittings a stepped bore is required. The lower part of the cover strip should be drilled with a d = 7 mm diameter. The upper part of the cover strip needs a d = 11 mm diameter for the screw head. It is recommended to install a washer (PA washer, e.g. Z 0033) with all screw fittings.\n

Flat cover strip DL 5073 / DL 6073

Tips for laying the cover strip
DL 5073 / DL 6073

We assume that this cover strip will be used with glass panes that are supported on two sides and the recessed screw head is concealed. In this case, a cylinder head screw with inner hex is to be used (e.g. M6 DIN 6912 stainless steel A2 with low head). When covering with a 2 mm cover plug Z 0089, a bore depth of 6 mm is calculated.

Depending on the precision of the bore, it should be decided on case by case basis if any slight changes to this depth are necessary. The cover plug Z 0089 does not need to be glued in place, but may be levelled using levelling compound.

Coating the cover strip

Profile production (aluminium extrusion moulding) with different mass distribution is extremely difficult. Lengthwise shadow formation may result. Resulting actions are to be taken with the agreement of the coater.

Intersections

Due to the special shape of the strip (the material extends into the rebate), there is no closed sealing section available at intersections. We therefore recommend placing particular attention to ensure tightness of the joints and fill with Stabalux connecting paste Z 0094.

Glass supports/blocking

Special attention should be given to dimensional proportions. Glass supports should be designed by the processor depending on the glass thickness and weight (e.g. for welded glass supports). To support the outer pane, a sufficiently large glazing block must be installed that can carry the load to safely ensure the glass load is distributed effectively.
**Use of slab insulation**

- Using insulation blocks significantly reduces heat dissipation.
- The highly effective slab insulation has a permanently adhesive HOT-MELT.
- Depending on the situation where they are used, insulation blocks can be directly applied to the cover strip/lower strip or placed into the rebate over the screw fittings and pushed into position with the cover strip/lower strip. The type of screw connection (bolt-socket-bolt) means that a groove must first be cut in the insulating block at the points of connection.
- With system width 80 mm and a 40 mm rebate 2x 20 mm wide slab insulation blocks can be combined (40 mm wide insulation blocks available upon request).

**Note:**

- The use of slab insulation with cover profiles DL 5073 / DL 6073 should be tested for each individual situation.
- 2-piece outer seals are always used with slab insulation blocks: for example outer seal GD 1932

Pane support variants

Special design

Glass structures that partially refrain from using visible cover profiles are considered special designs.

These designs do not conform to the intended uses of the system. No guarantees are made for e.g. quality of seals, durability and structural stability. Responsibility here lies entirely with the company implementing the design.

Based on our experience we recommend paying close attention to the points made on the following pages during planning and implementation.

Mullion-transom structure, 2-sided cover strip

1) Seals with 1, 2 or 3 sections are possible

2) Use of mullion seals with 1 section in mullions and transoms
Pane support variants

Vapour seal:

When using this type of structure, it is important to be aware that any loss of contact pressure can affect the room-side permeability. There is an increased risk of condensation build up in the rebate.

Vertical clamping strips

The glass supports should be placed below the outer pane and sealed with it.

Horizontal clamping strips

Ventilation and condensation drainage is achieved via a recess in the lower sealing lip in the centre of the outer seal or at one third intervals.

![Diagram of transom and mullion structure with cuts A-A, B-B, C-C, D-D]
Pane support variants

Design requirements

1 Vapour seal:

The room-side level of glazing must have the best possible vapour seal. In this regard, the vapour diffusion properties of the silicone sealant to be used should be tested.

Ensure that there are no permeable areas around concave cross joints.

2 Rebate ventilation, pressure equalisation and condensation drainage

Systems with partially sealed rebate represent a limitation to rebate ventilation. Check on a case-by-case basis that no damage will be caused by standing condensation. It is especially critical that designs with sealed vertical joints are evaluated. To allow ventilation of the horizontal rebate we recommend installing a suitable vertical ventilation space. Alternatively, ventilation can be achieved using the outer joints.

3 Weatherproofing

The outward facing seals must be watertight. In cross joints, it is especially important to ensure a firm join between the Stabalux profile seal and the silicone joints. We recommend sealing up to the outer edge of the glass before mounting the cover profiles.

We would like emphasise once again that our profile seals will not make a permanent bond with commonly used silicone sealants. A seal can only be created at contact points through permanent application of pressure.

4 Mechanical strength of the screw fittings

Ensure screw fittings are of a sufficiently size. Special attention should be given to the effects of wind suction and the reduced support.

5 Glass weight distribution

Mechanical distribution of the weight of the glass panes through the structure must be ensured. System glass supports can be used for existing horizontal transoms. Designs using "only" Mullions require special glass supports which carry the weight of the glass directly into the mullions.

6 Glass sizing

Attention should be given to the reduced support of panes when dimensioning the glass. For example, only the vertical or horizontal cover profiles are effective in the event of wind suction stresses or stress on the fall protection.

7 Material compatibility

Compatibility of the silicone sealants with our profile sealants and the edge bonding of the glass must be ensured. We recommend the exclusive use of tested silicone sealants from the whole-glass facades sector. Approval is usually given by the silicone manufacturer.
Examples:

1. Vertical glazing, mullion concealed screw fittings
2. Vertical glazing, mullion visible screw fittings
3. Vertical glazing, mullion flat cover strip DL 5073 / DL 6073
4. Vertical glazing, transom, visible recessed screw fittings, Outer seal for height compensation
5. Vertical glazing, transom, concealed screw fittings, single glazing,
6. Vertical glazing, transom, concealed screw fittings,
7. Inclined glazing, mullion, concealed screw fittings
8. Inclined glazing, transom visible screw fittings
System details

Creating facade corners

At exposed areas such as glass facade corners, it is particularly important to ensure sufficient heat insulation in order to avoid the creation of thermal bridges and prevent a build-up of condensation. Thermal current calculations provide information about the actual heat loss.

Facade polygon

Special seal allow a polygon shaped arrangement of the facade mullions. For convex glass surfaces an angle between 3° and 15° can be freely chosen. For concave glass surfaces the angle can vary between 3° and 10°.
System details

Eaves with glass roof connection

- Depending on the construction of the transoms, a design with or without rain gutters and the choice of stepped glazing or closable cover profiles gives us different variants for implementation.
- All options require condensation and moisture to be drained away at the eaves.

Design with stepped glazing

- With a stepped glazing design it is important to select a UV-resistant edge bonding for the glass. This edge bonding systems, usually silicone-based, are quite permeable to gases and are therefore unable to achieve the required high values for sound and heat insulation of conventional systems, i.e. require additional sealing around the edges.
- Our thermal calculations show that stepped glass panes, compared to covered glass edges, have a much less favourable isothermal movement.
- Stepped glass panes must also be statically measured according to their reduced hold against wind suction.
- The additional thermal loads that occur in stepped glass panes should countered by the use of pre-tensioned glass (TVG, ESG) for the outer panes.
- Stepped glass panes should be preferred for flatter inclined roofs as water can drain away at the eaves unhindered.

Example 1:

Design with stepped glazing
Eaves with glass roof connection
Design using cover profiles

- Horizontal pressure strips prevent the free run off of rain water and dirt.
- Cover strips with angled edges reduce the build up of water in front of the cover strip.
- The outer sealing level on glass roofs must also be thoroughly sealed.
- In combination with our butyl clad stainless steel panels, glazing with pressure strips on 4 sides achieves a higher level of safety.
- Make sure that the inner sealing section provides guaranteed drainage for condensation.

- To improve drainage and heat-induced expansion, cover profiles should be shortened by 5 mm at transom joints. Gasket joints, however, are to be laid flat with a slight excess in dimensions. Open ends of the transom cover profiles must be sealed.

Note:
Due to the increased thermal stresses in the roof, we recommend using concealed screw fitting when choosing clamping strips for larger system lengths and in rafters. Unused holes in the lower strip must be sealed.

Example 2:
Design using cover profiles

Note:
Glazing at an angle of ≥10° from vertical position must conform to a glass structure for overhead glazing!

Glass support according to glass thickness!
System details

Eaves with glass roof connection
Design with gutter

- The gutter must be able to take its own weight and mounted in such a way that stresses from its own weight, water and ice will not lead to deformations and directly apply a load to the glazing.
- Overflowing water must not be able to get inside the structure. Alongside the gutter-shaped outer rafter seal, the moisture barrier installed over the guide plate also acts to drain away condensation.

Example 3:
Design with gutter
Roof ridge design

- When designing the ridge cap, ensure that the rafter cover profiles are pulled under the ridge cap.
**Structural attachments**

**Structural attachment film baffles**

- Attachment of glazing to the building structure requires a well thought out approach.
- Moisture damage can occur if moisture condenses at any thermal bridges.
- Thermal bridges must be avoided and warm air from the inside spaces must not penetrate too deeply into the structure.
- The required moisture barriers must be installed as deeply as possible into the inner space using impermeable structural film baffles. This prevents moisture penetration into the structure via condensation from the air inside.
- An additional foil to seal against rainwater must be permeable to moisture. Only if this foil has a water vapour diffusion resistance value $\mu$ of max. $\mu = 3000$ can a dry structure be guaranteed in the transition zones.
Facade base

- Controlled drainage of the rebate space can only be ensured if the sealing sections overlap in such a way that no moisture can get under the seals and foils.
- Run foils under the transom seal to act as a moisture barrier and glue to the steel structure. In accordance with DIN 18195 the seal should be run at least 150 mm above the water-guiding layer.
- Attach foil with moisture barrier in accordance with the requirements of DIN 18195.

Example 1:

Mounting intermediate mullion to base plate

Drainage of the base area is achieved via the transom flag towards the outside. In this case the transom flag around the mullion at the base should not be released. For edge mullions, ensure there is a corresponding seal placed (continuous transom seal up the to the end point) and a constructive design of the drainage section.
Structural attachments

Facade base

- Rebate space ventilation is achieved via the open end of the vertical cover profiles.
- Ensure the connection is impermeable to vapour.
- Mullion mountings must be sufficiently statically dimensioned. Required axis and edge distances for anchoring the base plates and in the building structure must be observed.

Example 2:

Mounting intermediate mullion to base plate

Where transom flags are interrupted by joints, filler rods in the joint must also be cut.
Structural attachments

Facade base

- Heat insulation around the structural connection should be designed in such a way as to prevent cold bridges forming.
- Steel parts should also be provided with sufficient protection against corrosion even in concealed areas.
- Weather-protection sheets should be used depending on the requirements of the construction. Sufficient rear ventilation must be ensured.

Example 3:

Attaching intermediate mullions at base plates
Connection before intermediate floors

- Depending on requirements, mullions are designed as continuous multi-span transoms or separated at each floor.
- Reasons for separating mullions can include e.g. building settlement, fire protection, sound insulation, etc.
- If the separation joint is intended to absorb expansion, then as well as the required degree of freedom for mullions the ability for movement of integrated elements must also be ensured.

Example:

Mullions separated at each floor

In this example, distribution of horizontal and vertical loads is achieved at each floor through the existing floor structure.
Structural attachments

Ceiling connection

- Structural connections should take account of any movement that may occur.
- As well as temperature induced expansion in the facade, all longitudinal expansions and movements of the affected components must be considered.
- Additional stresses from restraints must be avoided.

ZL-S_2.3_012.dwg
Connection to structural eaves

- This connection is suitable for glass roofs that are being installed as skylights in the structure. These may be gabled roofs, single pitch roofs, pyramids or arched roofs.
Ridge connection to walls

- When making ridge connections to walls, permeability to moisture is particularly important. Warm air with a high level of moisture gets into cooler zones of the inner sealing section where the design is not sufficiently sealed and can cause structural damage from penetrating into the connecting structure.
- Joint seals made from butyl-clad stainless steel plates (Z 0501, Z 0601) must be installed on the outside of joint areas.

Stabalux ZL-S  Design 01.07.2020
Installing windows and doors

Mullion and transom facades and glass roofs from Stabalux are neutral with regards to the selection of insert elements. All commonly available window and door systems made from steel, aluminium, wood or plastic can be used. Frame profiles from the window and door manufacturer’s should be selected to match the chosen glass thickness. If no profiles with a suitable insert rebate are available, mountings may be used as shown in the following examples. Like with glass elements, windows are set into the facade on glass supports, padded and then secured against slippage.
